Scope

The purpose of this document is to give a brief overview of the primary security considerations that have been incorporated into the Insight Remote Support (RS) solution. If additional security information is required, please refer to the Security White Paper document for your software version. These documents can be found in the White Papers section for each version of Insight Remote Support listed in the documentation library shown below.

Insight Remote Support: <http://www.hp.com/go/insightremotesupport/docs>.

Insight Remote Support monitors and reports hardware events, collects information for proactive data analysis, and provides the ability to allow secure remote access into your IT environment for HP support personnel.

Insight Remote Support software uses industry standard security techniques to ensure privacy and security of your data.

Overview

The HP Insight Remote Support solution is composed of three primary components:

- Remote Device Monitoring (RDM)
- Remote Data Collection (RDC)
- Remote Device Access (RDA)

Each of these components is described in this document. In addition to the three main components, information is provided on software management, application security, outbound communications, inbound communications, and data handling security.

Remote Device Monitoring

Remote Device Monitoring monitors your environment for hardware events. If an event requires HP intervention such as a hardware failure, it is automatically sent to HP for processing where it is acted upon as per the service level agreement. Systems supported by the Insight RS solution include servers, storage devices, network devices, and selected multivendor products. A detailed list of supported hardware devices can be found in the release notes for your specific software version at the URL shown on page 2 of this document.

Events sent to HP do not contain business data. Event information contains device specific information (fault information and configuration details) for the failing device. This information will also include device identification and contact information such as IP address and fully qualified domain name, device administrator contact names, email addresses, and phone numbers. To ensure that HP customer information is properly protected, HP has implemented a range of industry standard security techniques that are described later in this document.

Remote Device Monitoring monitors your IT environment for hardware events.

Remote Data Collection

Remote Data Collection has two purposes. Its first purpose is to collect device information (logs, configuration information, etc.) to aid HP Support in the proper diagnosis of a failure. This basic data collection is performed using standard web management tools like Web Based Enterprise Services (WBEM) and Simple Network Management Protocol (SNMP). This level of data collection is standard for all Insight Remote Support installations.

Remote Data Collection can also be enabled for proactive service contracts. These enhanced data collections collect information about the systems or environment and send the data to HP for analysis. The data is analyzed by HP and is used to provide proactive assessment reports about your IT environment, such as system health checks, current patching levels, firmware revision reports, system audits, and availability reports. These reports are intended to be used to help manage your IT environment and increase the overall availability of the systems in your IT enterprise.

Remote Data Collection collects device information to aid HP Support in the proper diagnosis of a failure. Enhanced data collections enable proactive assessment reporting for your IT environment.

Remote Device Access

Remote Device Access allows an HP engineer the ability to securely access your environment to perform additional failure analysis and/or problem resolution. It can also be used by your HP account team to access your environment to deliver proactive support and/or upgrade services. For reactive purposes, once an issue has been identified, a remote support engineer may need access to the failing device to assist with the repair or to collect log files. Historically, this was done either by sending an engineer onsite to access the system locally, or by an HP Support Representative working with your IT staff over the phone to collect and review the failure information. However, with Remote Device Access, HP can make use of a customer controlled connection to access the customer network. This frees up your IT staff to work on other tasks, reduces repair time, and allows the HP experts direct access to the device resulting in more accurate problem diagnosis and faster resolution of issues.

Most of the HP remote access solutions use a connection over the internet and it is therefore vital to protect both customer's as well as HP's confidentiality, integrity, and availability. For this, HP offers a number of industry standard, secure remote access solutions (depending on the service level agreement) to help meet customers' IT security policy requirements.

Remote Device Access allows HP to securely access your environment to perform additional troubleshooting and/or problem resolution.

Software Management

HP Insight Remote Support uses a built in software management component that is intended to be used to manage the Insight Remote Support software components. The software update utility is a component that can be configured to manage software updates in any one of three ways:

Manually Apply: Notifies the Hosting Device Administrator when a new software package update is available. Updates are manually downloaded and installed by the Hosting Device Administrator.

Automatically Download: Notifies the Hosting Device Administrator when a new software package is available and automatically downloads the package. Updates are manually installed by the System Administrator.

Automatically Download and Install: Updates are automatically downloaded and installed on the Hosting Device. The Administrator is notified that the software update has been installed.

Software Management enables you to choose how to manage Insight Remote Support Software.

Application Security

HP Insight Remote is a software application that utilizes an existing Windows® server (known as the Hosting Device). Since the Hosting Device is customer owned and installed, it can be configured to meet your Windows® server security policy. It is important that the integrity and authenticity of the Insight Remote Support software is maintained to prevent unauthorized changes. Therefore, all updates downloaded by Insight Remote Support software update mechanism are digitally signed by HP prior to release. The digital signatures are verified prior to installation.

All Insight Remote Support software packages are digitally signed by HP. The digital signatures are verified prior to installation of the software.

Outbound Security

Insight Remote Support software collects event information from all monitored devices. Only events requiring HP interaction will be forwarded to the HP Remote Support Datacenter (RSDC). All communication between the Hosting Device and the RSDC are secured using industry standard SSL/TLS over HTTPS and are initiated by the Hosting Device. External firewalls must be configured to allow HTTPS traffic (outbound) between the Hosting Device and the universal URL of the HP RSDC (<https://services.isee.hp.com>). More information can be found in the Hosting Device Communication Requirements section of the Installation and Configuration guide.

All Insight Remote Support outbound communications are encrypted using SSL/TLS over HTTPS and authenticated with X.509 digital certificates.

RDM and RDC are designed to only require an outbound HTTPS connection. No inbound connections are necessary for these components to function. All connections are made using industry standard SSL/TLS encryption ensuring confidentiality and integrity of the information. X.509 certificates are used to authenticate both ends of the connection before any data is transmitted to the HP RSDC.

All communications for event monitoring and data collection are initiated from your enterprise to HP.

Inbound Security

RDA requires an inbound connection from the HP Remote Access Connection Server (RACS) to your designated access server(s). HP understands that IT security requirements are unique to every customer. Therefore, HP offers a number of remote access solutions (depending on the service level agreement) that are designed to meet most security policy requirements. All of HP solutions use industry standard techniques to ensure a secure remote access connection that includes one or more of the following secure (encrypted) protocols: Secure Shell (SSH), IPSec, Secure Sockets Layer (SSL), or Transport Layer Security (TLS). HP offers both hardware and software solutions which can be configured to ensure that you are always in control of the connection. We also offer options that allow you to view and monitor the HP engineer activities on your system and to set automatic timeouts for active connections.

HP offers a number of remote access options designed to meet your corporate security requirements.

All HP engineers accessing customer systems must adhere to the same standards of business conduct as onsite HP engineers, and are only allowed to attempt a remote access connection with customer approval and a valid business need. If your company has an assigned HP Account Support Team, it is possible to restrict the access to only the HP engineers assigned to your team. Internally, HP requires 'two factor' authentication to access to the remote access server and maintains logs of all RDA connections. HP engineers are only allowed to access the Remote Access infrastructure if they are members of certain role based groups in the HP LDAP directory. Access is limited depending on the group the HP Support engineer is assigned to.

Data Handling Security

It is important that HP maintains the availability of the Insight Remote Support infrastructure and collected data. This is provided by HP Remote Support Data Center (RSDC) which utilizes highly available server configurations in redundant data centers. All collected data is treated as HP Confidential information while at HP. As required by HP data privacy policies, the data is kept encrypted in the storage database and on backup media. It is never shared with third parties or used to increase profit. Access to the Insight Remote Support infrastructure is strictly controlled and only authorized HP engineers have access to the collected data, analysis systems, and reports.

HP treats your data as confidential and ensures that it is protected when stored at HP (in the database and on backup media)
